

TrekServ – Backend Team Contributors:

The backend of TrekServ was completely developed using Supabase, with Ipfi leading the backend team while reporting to Wanga, the project manager. The database was initially designed on paper, employing normalization principles and an Enhanced Entity-Relationship Diagram (EERD). This design was then implemented directly in Supabase's table editor, rather than using raw SQL scripts. To enhance security, Row-Level Security (RLS) policies were applied to every table and storage bucket, along with stricter password requirements at the authentication layer. Before starting development, the entire team participated in peer-led training sessions to become familiar with Supabase.

Contribution Breakdown

Team Member	Area	Details
Dembe	Database design	Designed the full database structure for TrekServ using normalization and an Enhanced Entity-Relationship Diagram (EERD), covering the user-facing side of the app: reports, community posts, events, polls, report images, categories, likes, and saved posts. Proposed and specified the community, comments, and likes/polls tables. Also contributed directly during table building and linking, advising on how the design translated into the live schema
Thato, Dembe & Ipfi	Table building & linking	Built the database tables in Supabase together, working from Dembe's EERD design, using Supabase's table editor rather than raw SQL. Jointly linked the relationships between tables using Supabase's built-in relationship/foreign-key tools
Duncan & Ipfi	RLS policies	Worked together to build out Row-Level Security policies for every table in the database, using Supabase's policy editor.
Ipfi	Storage & bucket security	Designed and built the storage buckets in Supabase and configured their RLS policies to control file access.

Wanga	Project management/backend oversight	Oversaw backend activities as project manager, including system health, optimization, overall structure, and how components connected.
